

Empirical departure probability by stage–spell age

Spell age counts consecutive documented transitions in the current stage

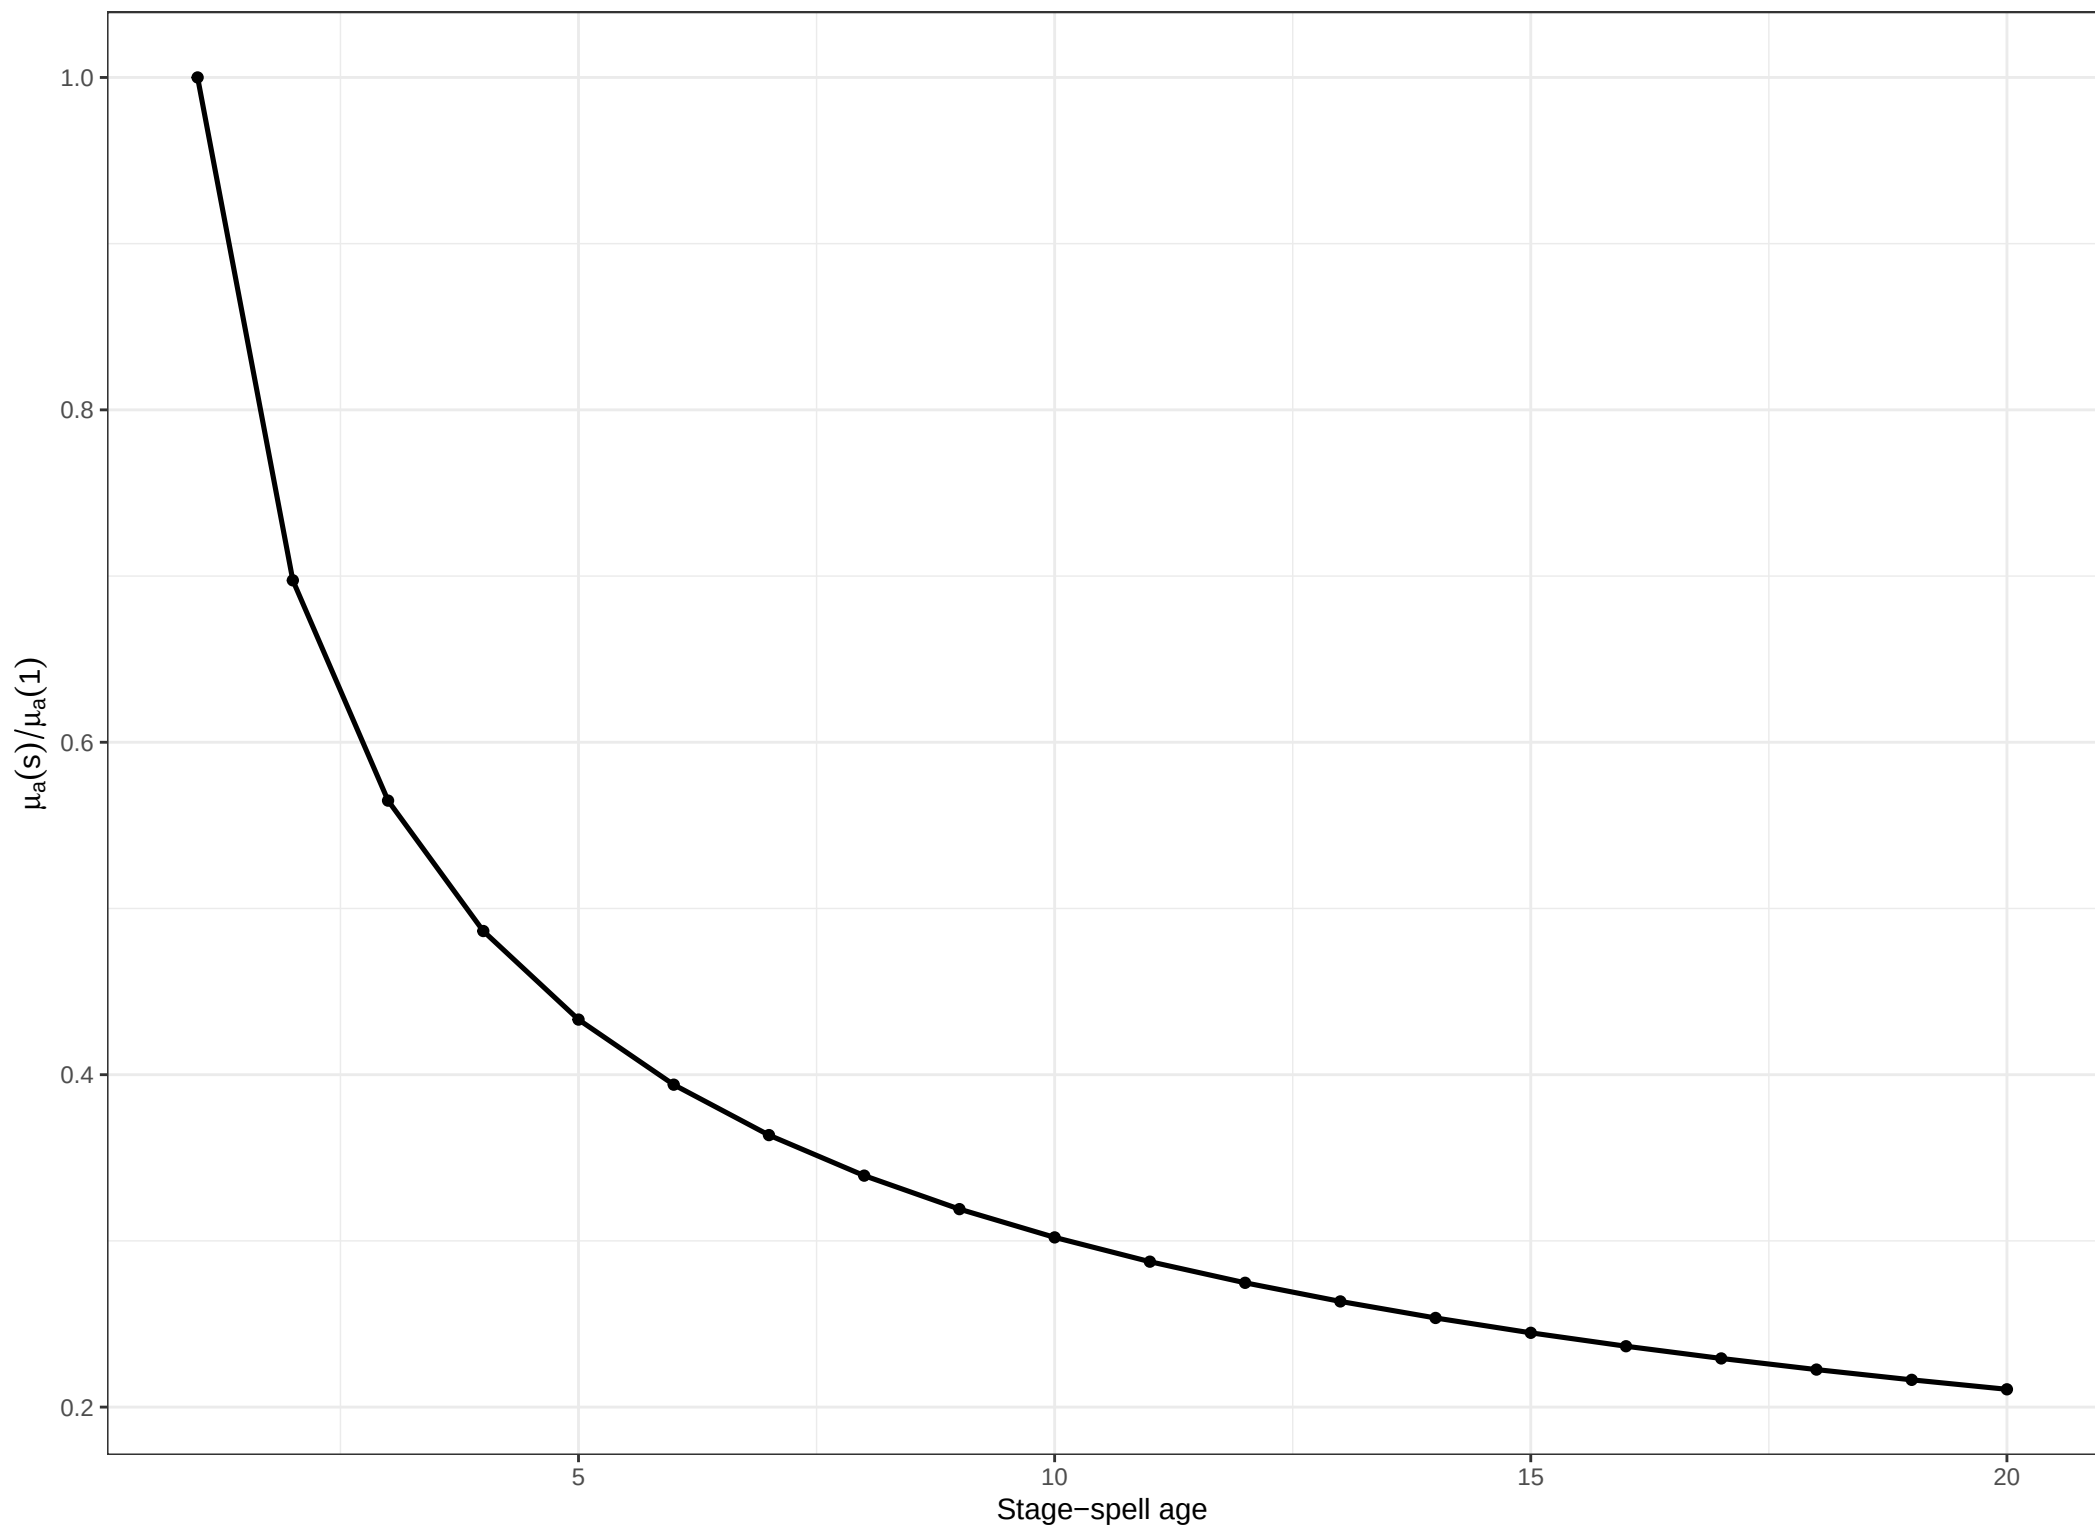

Stage-specific fitted departure profiles under SS-SPAOM

Common spell-persistence estimate $\beta = 0.5198$

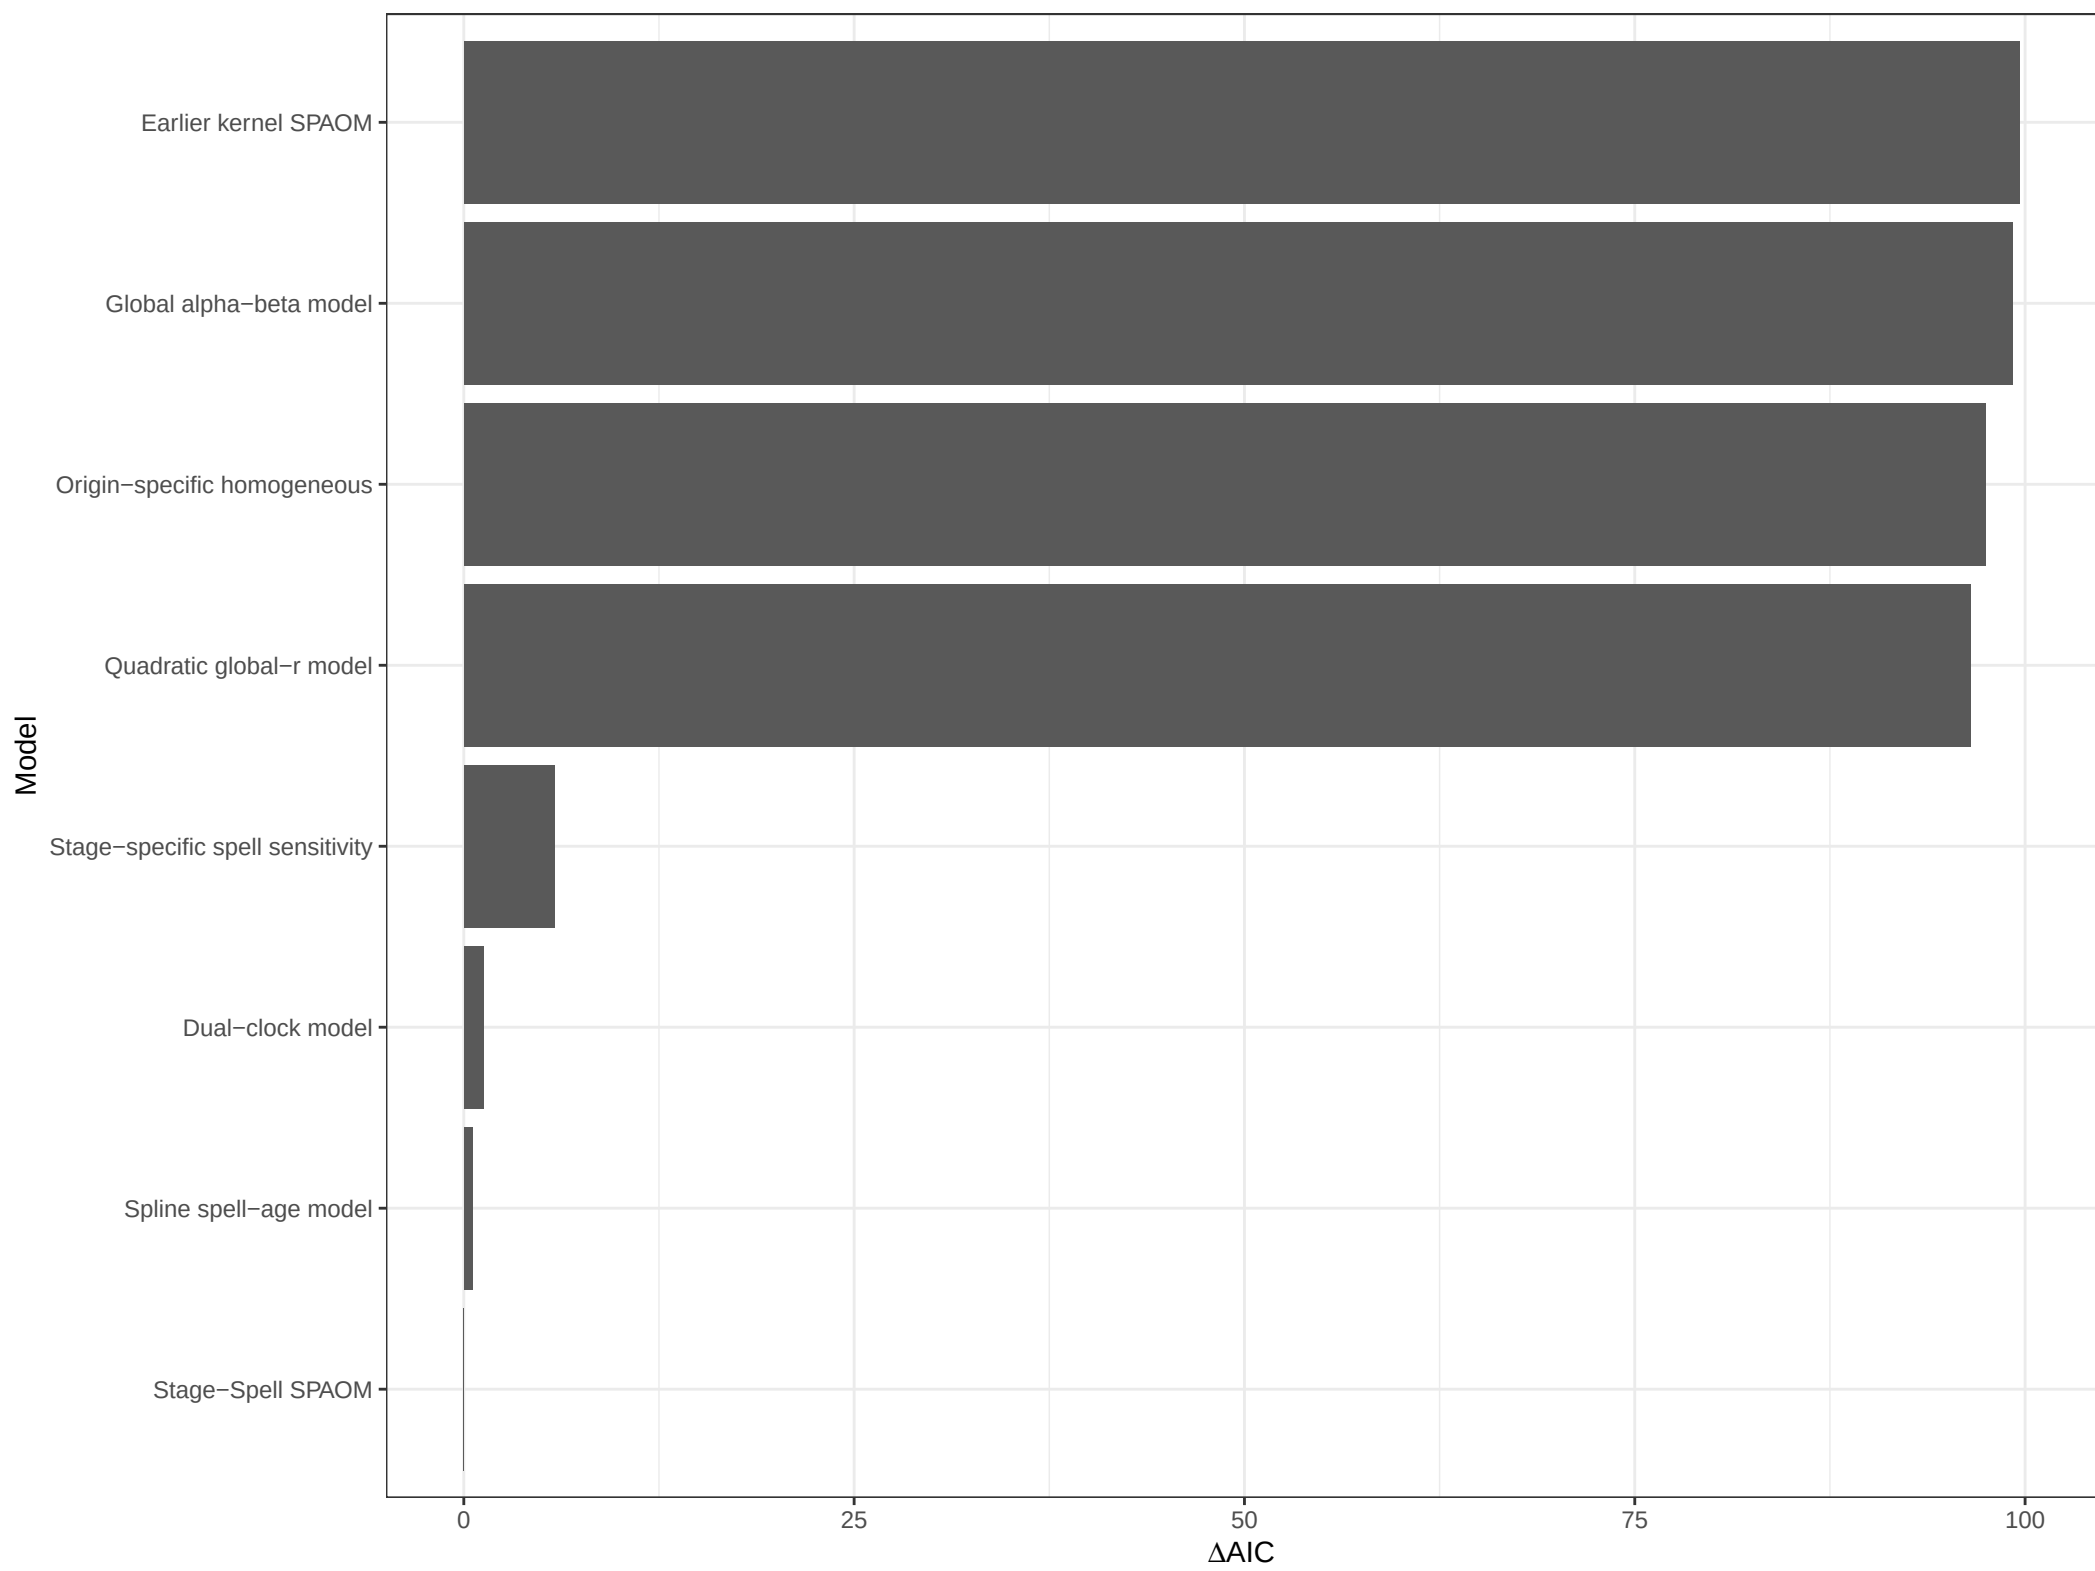

Estimated decline in opportunity intensity across a stage spell

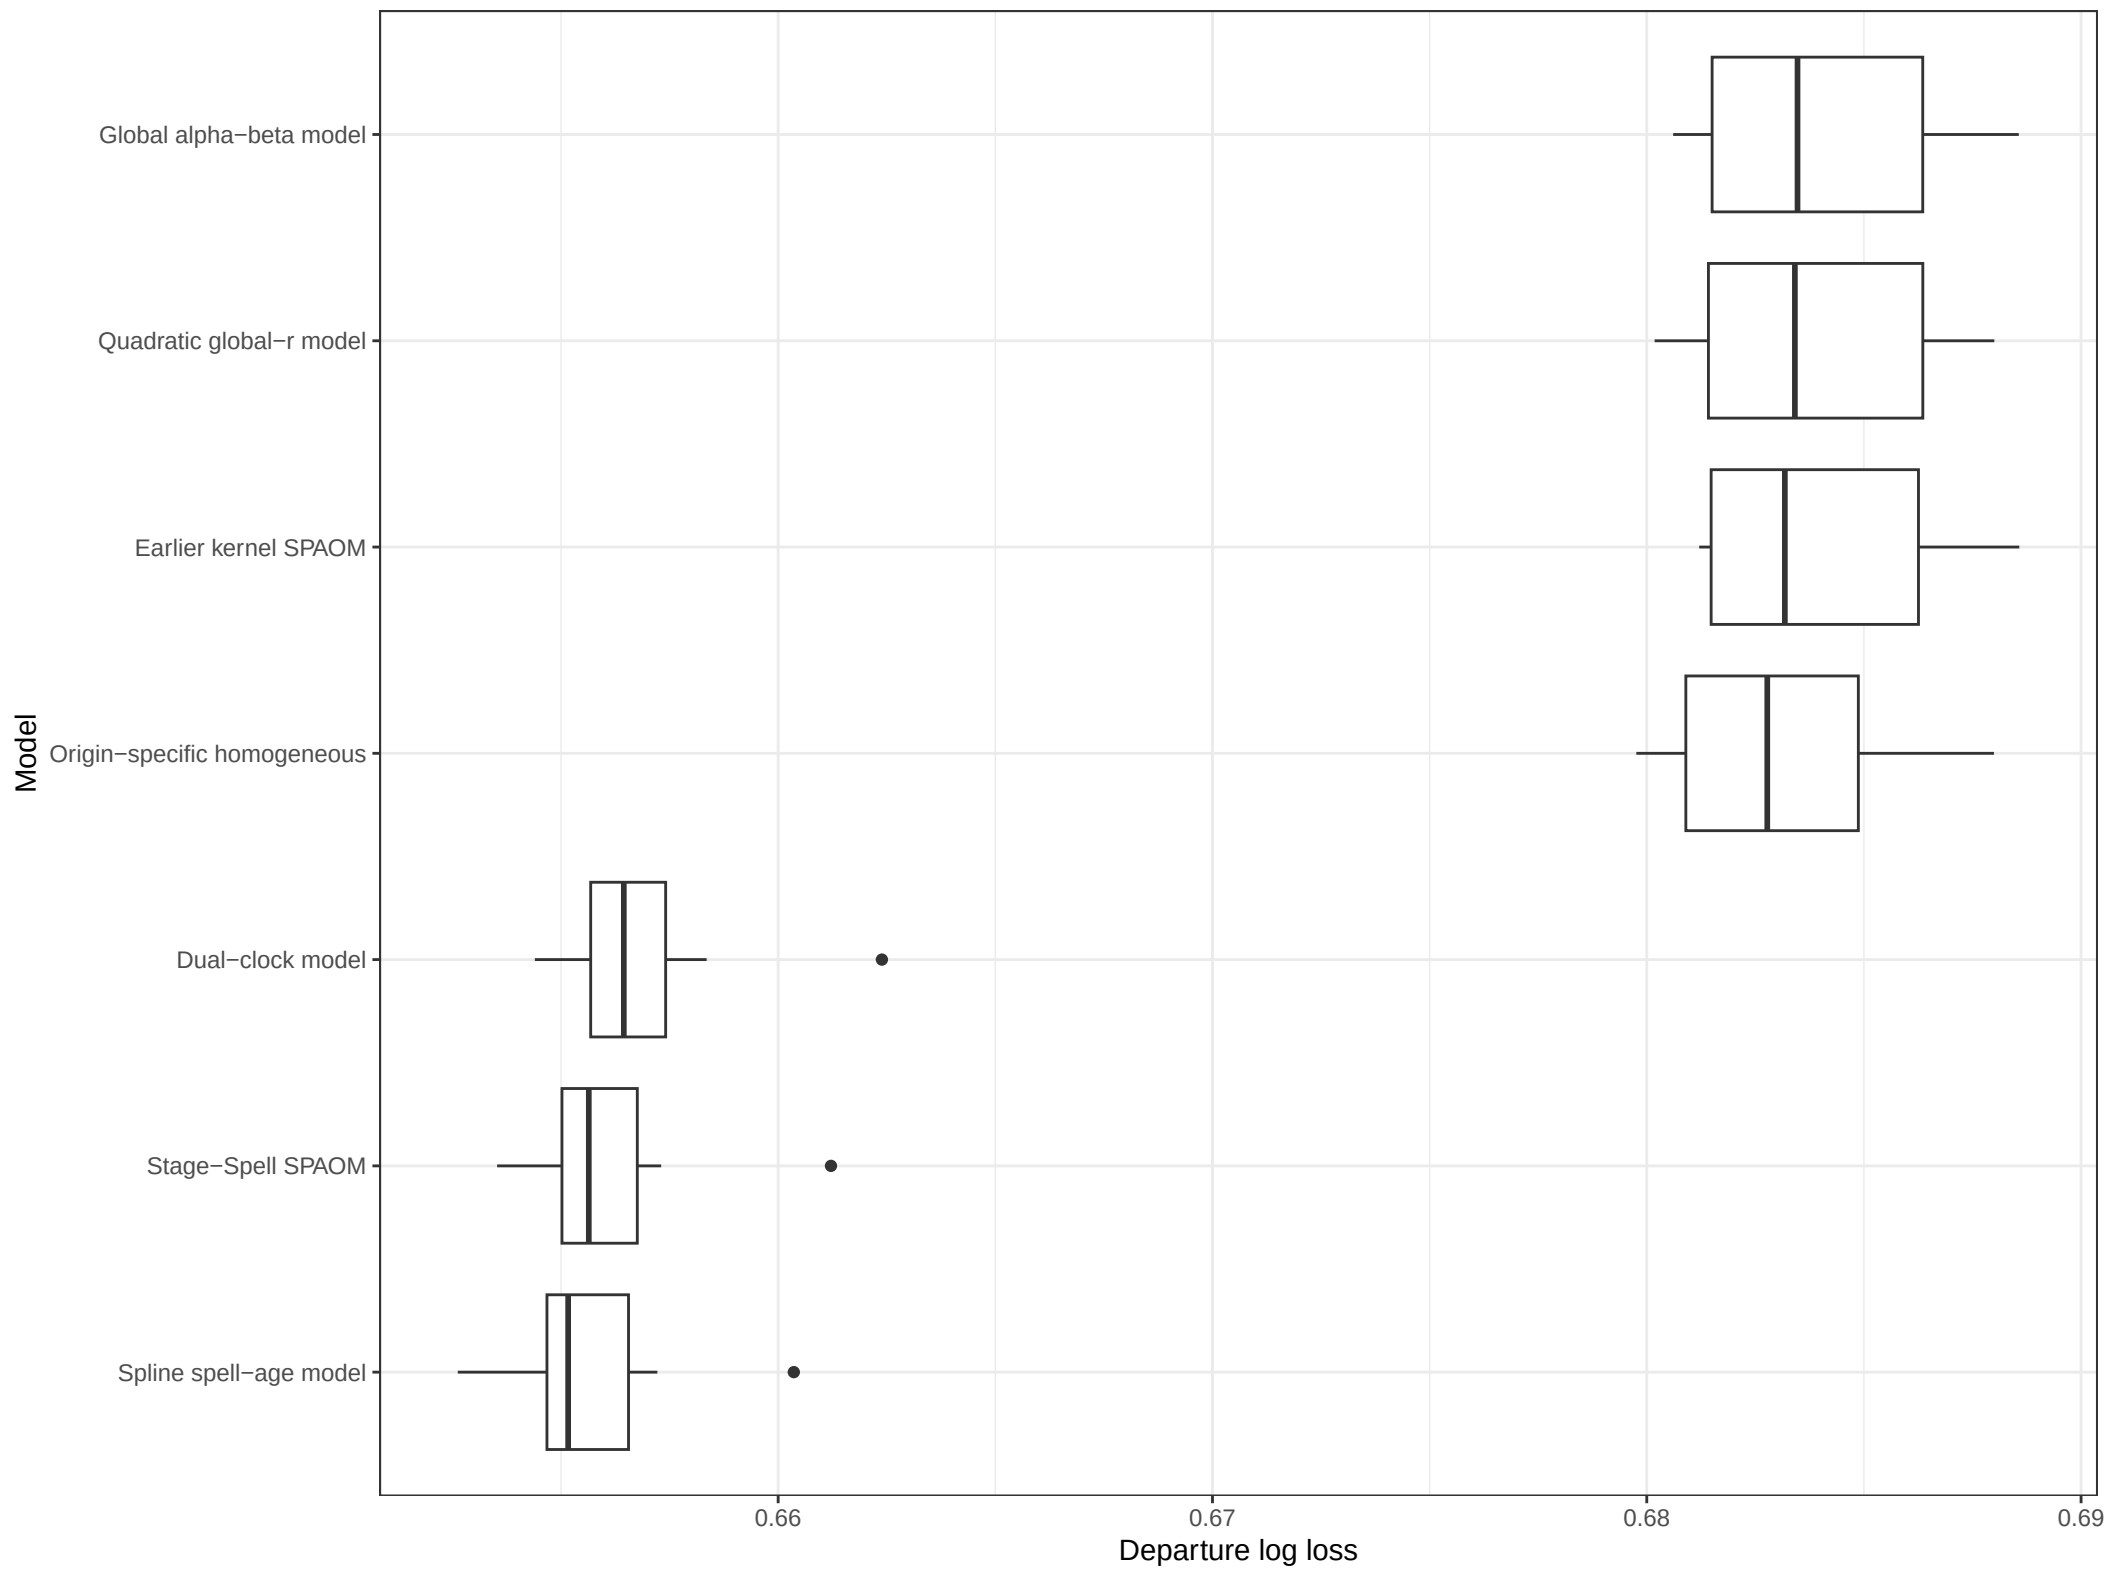

Values are relative to spell age one

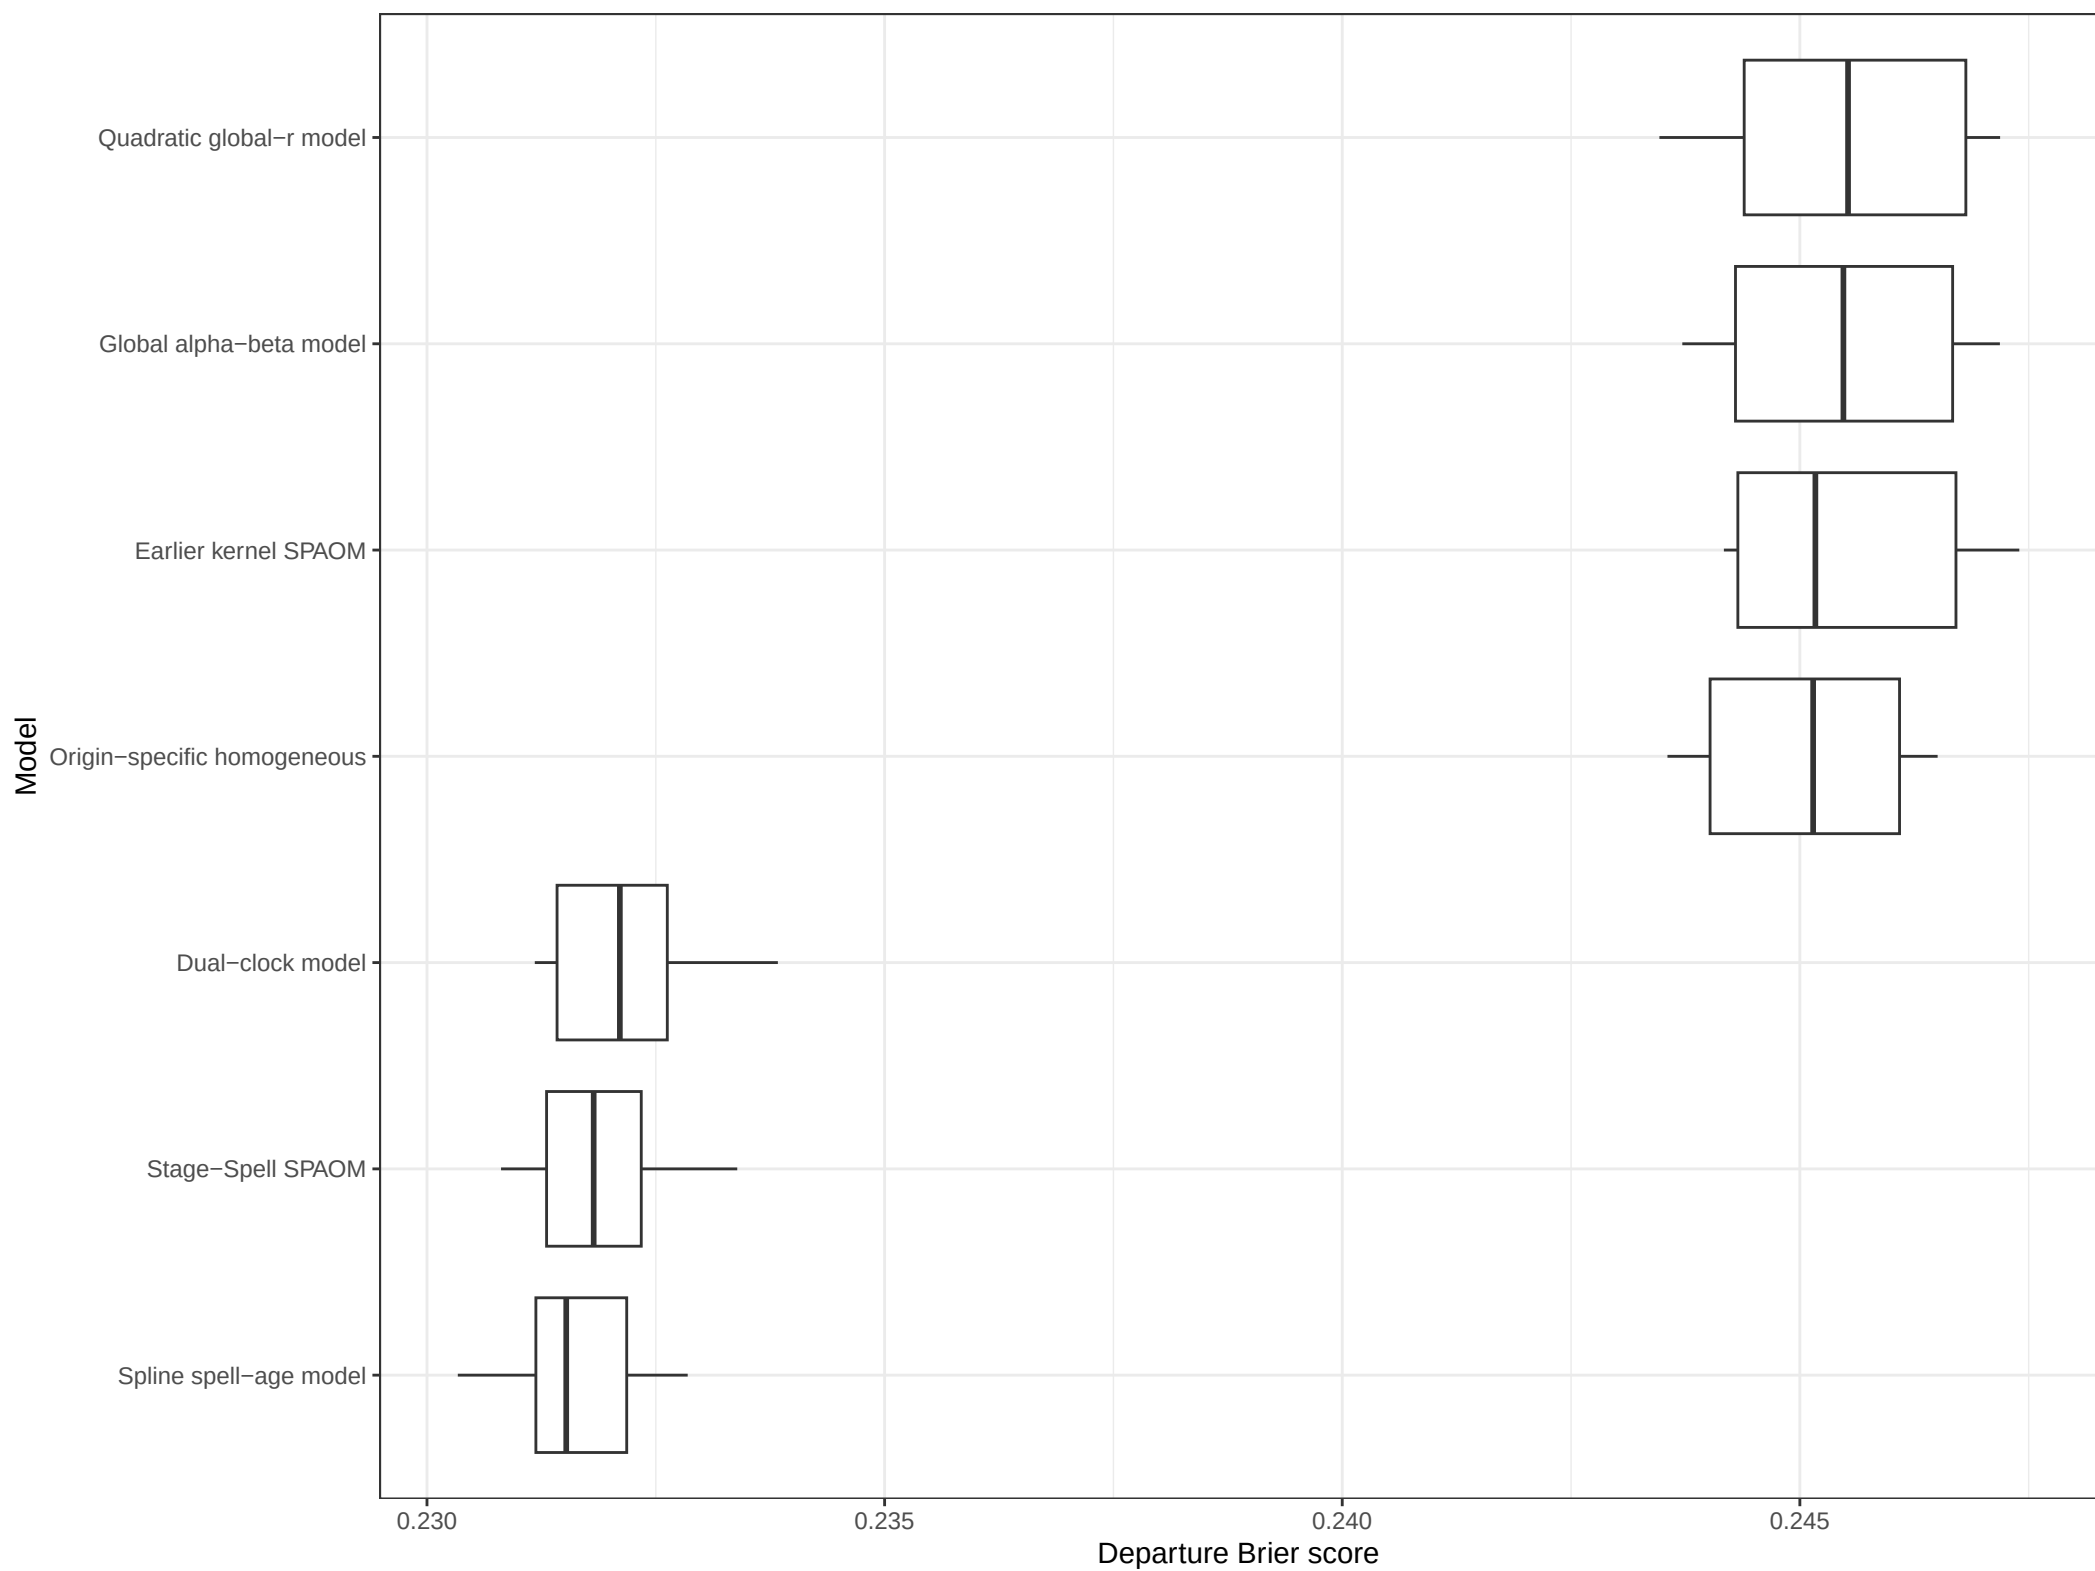

Departure-model comparison by delta AIC

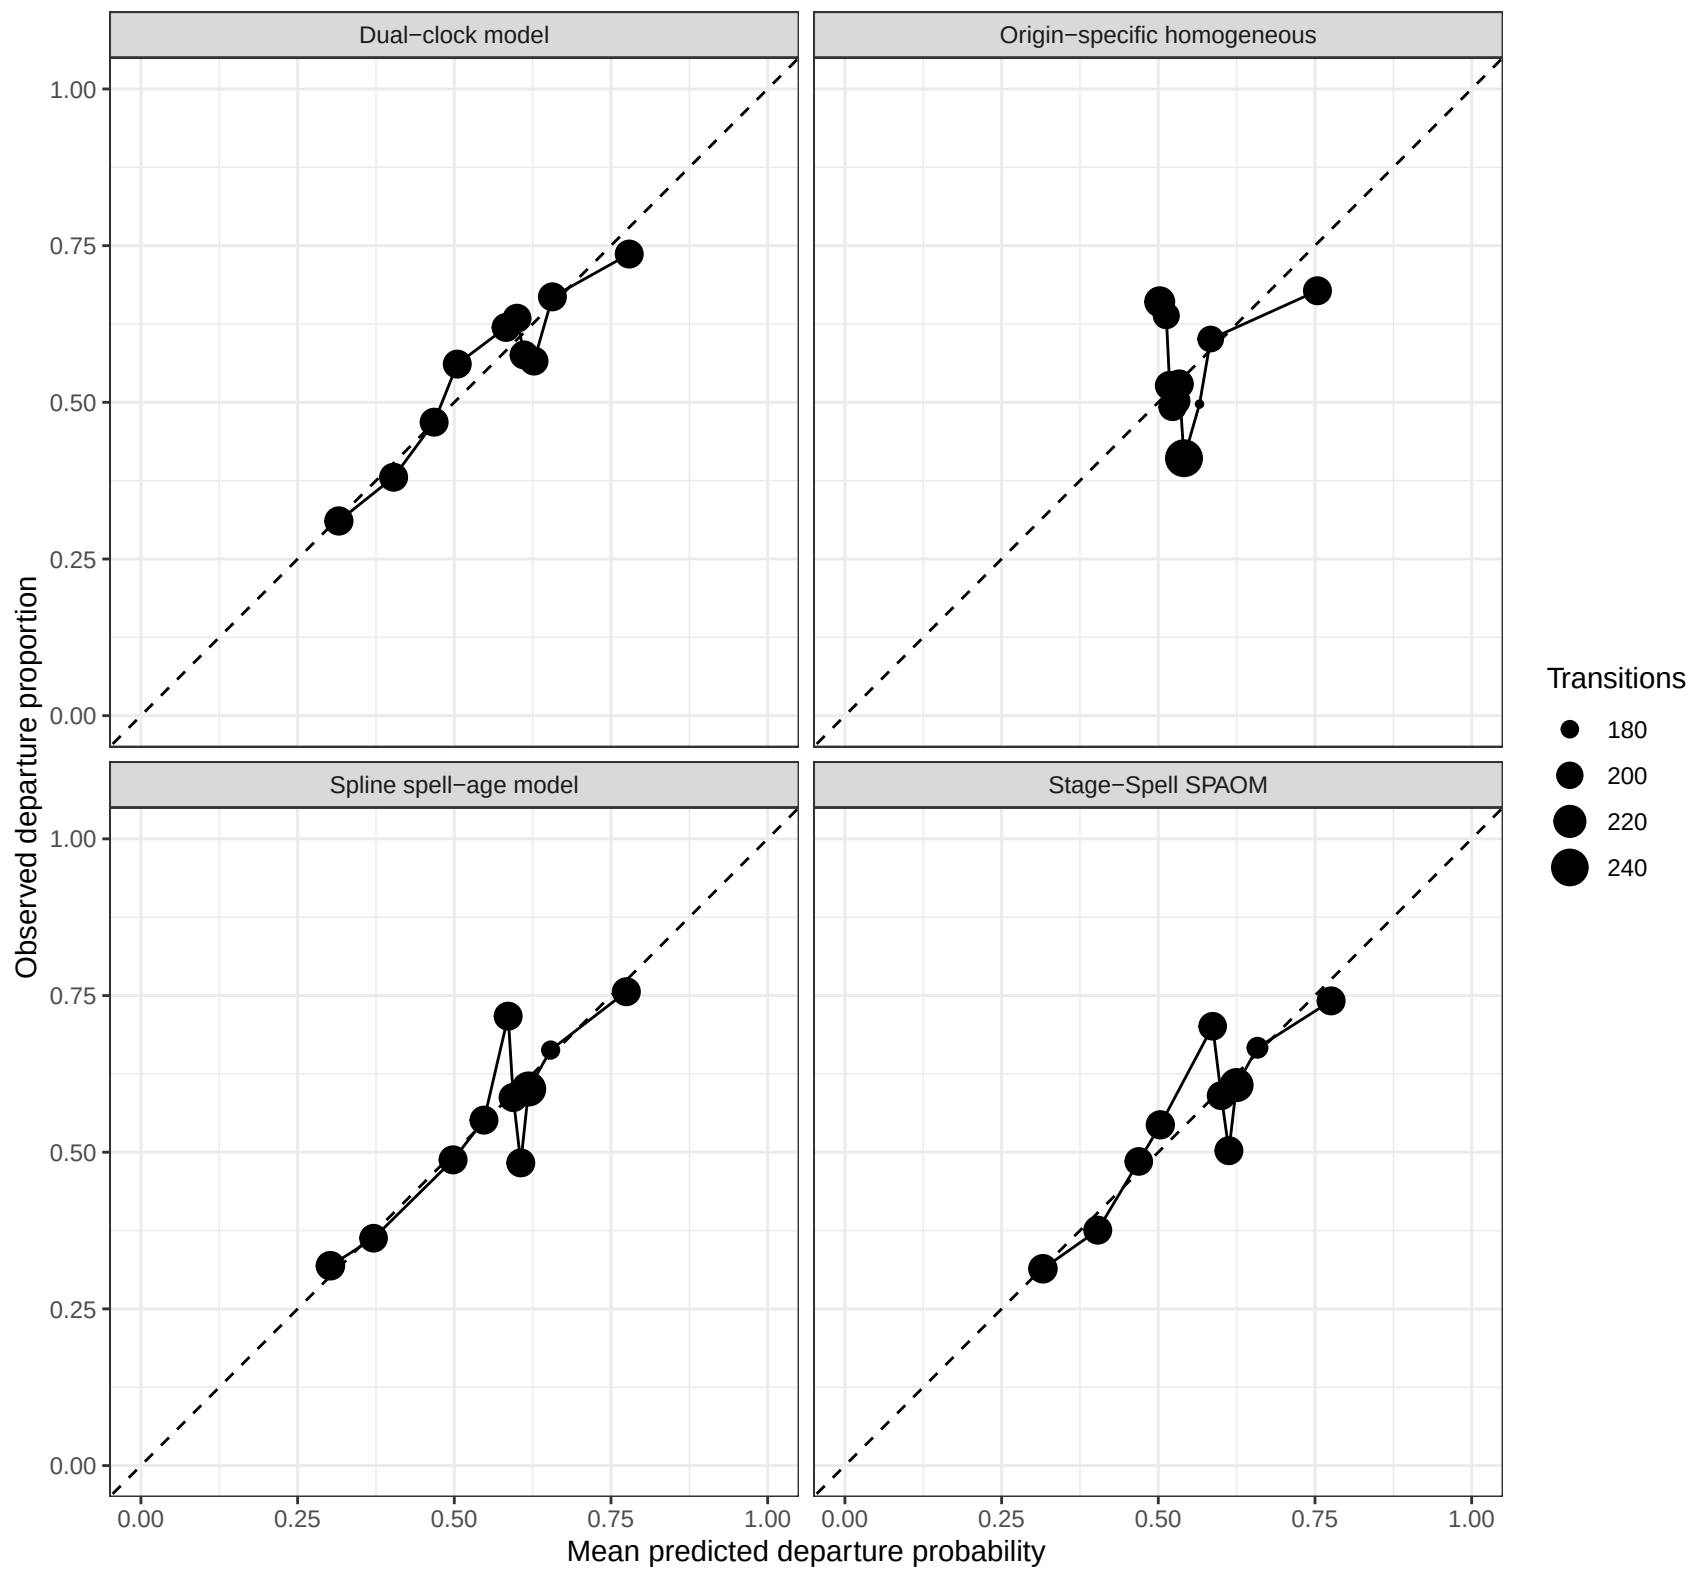

Repeated process-level cross-validated departure log loss

Repeated process-level cross-validated departure Brier score

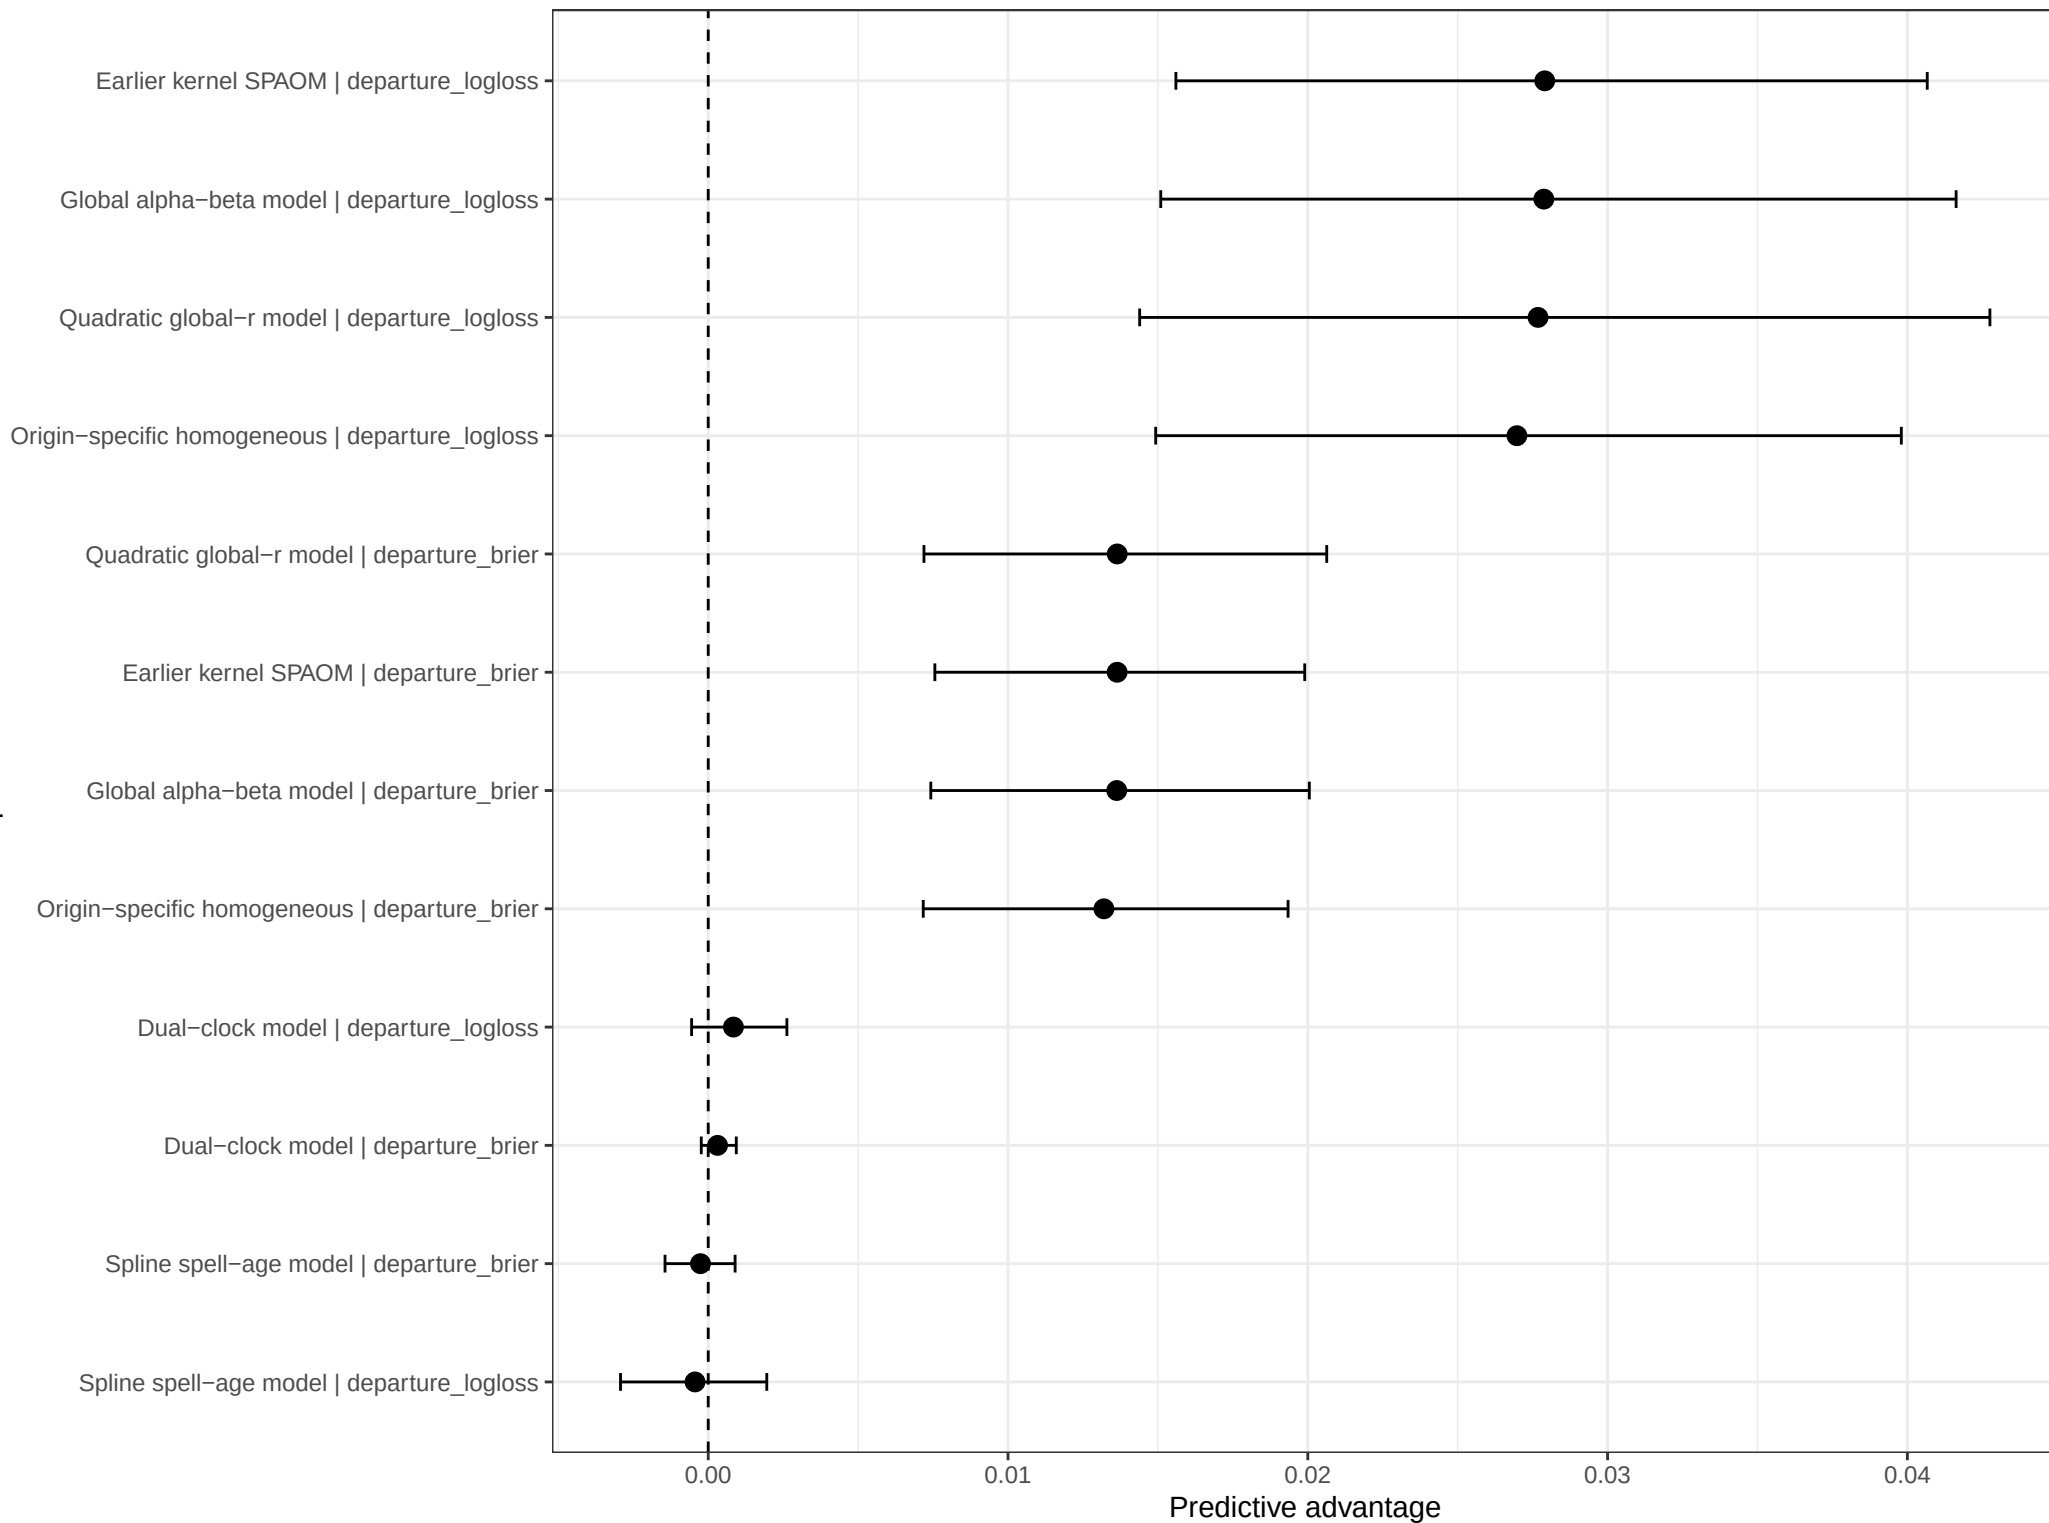

Cross-validated departure calibration

Paired predictive advantages of SS-SPAOM

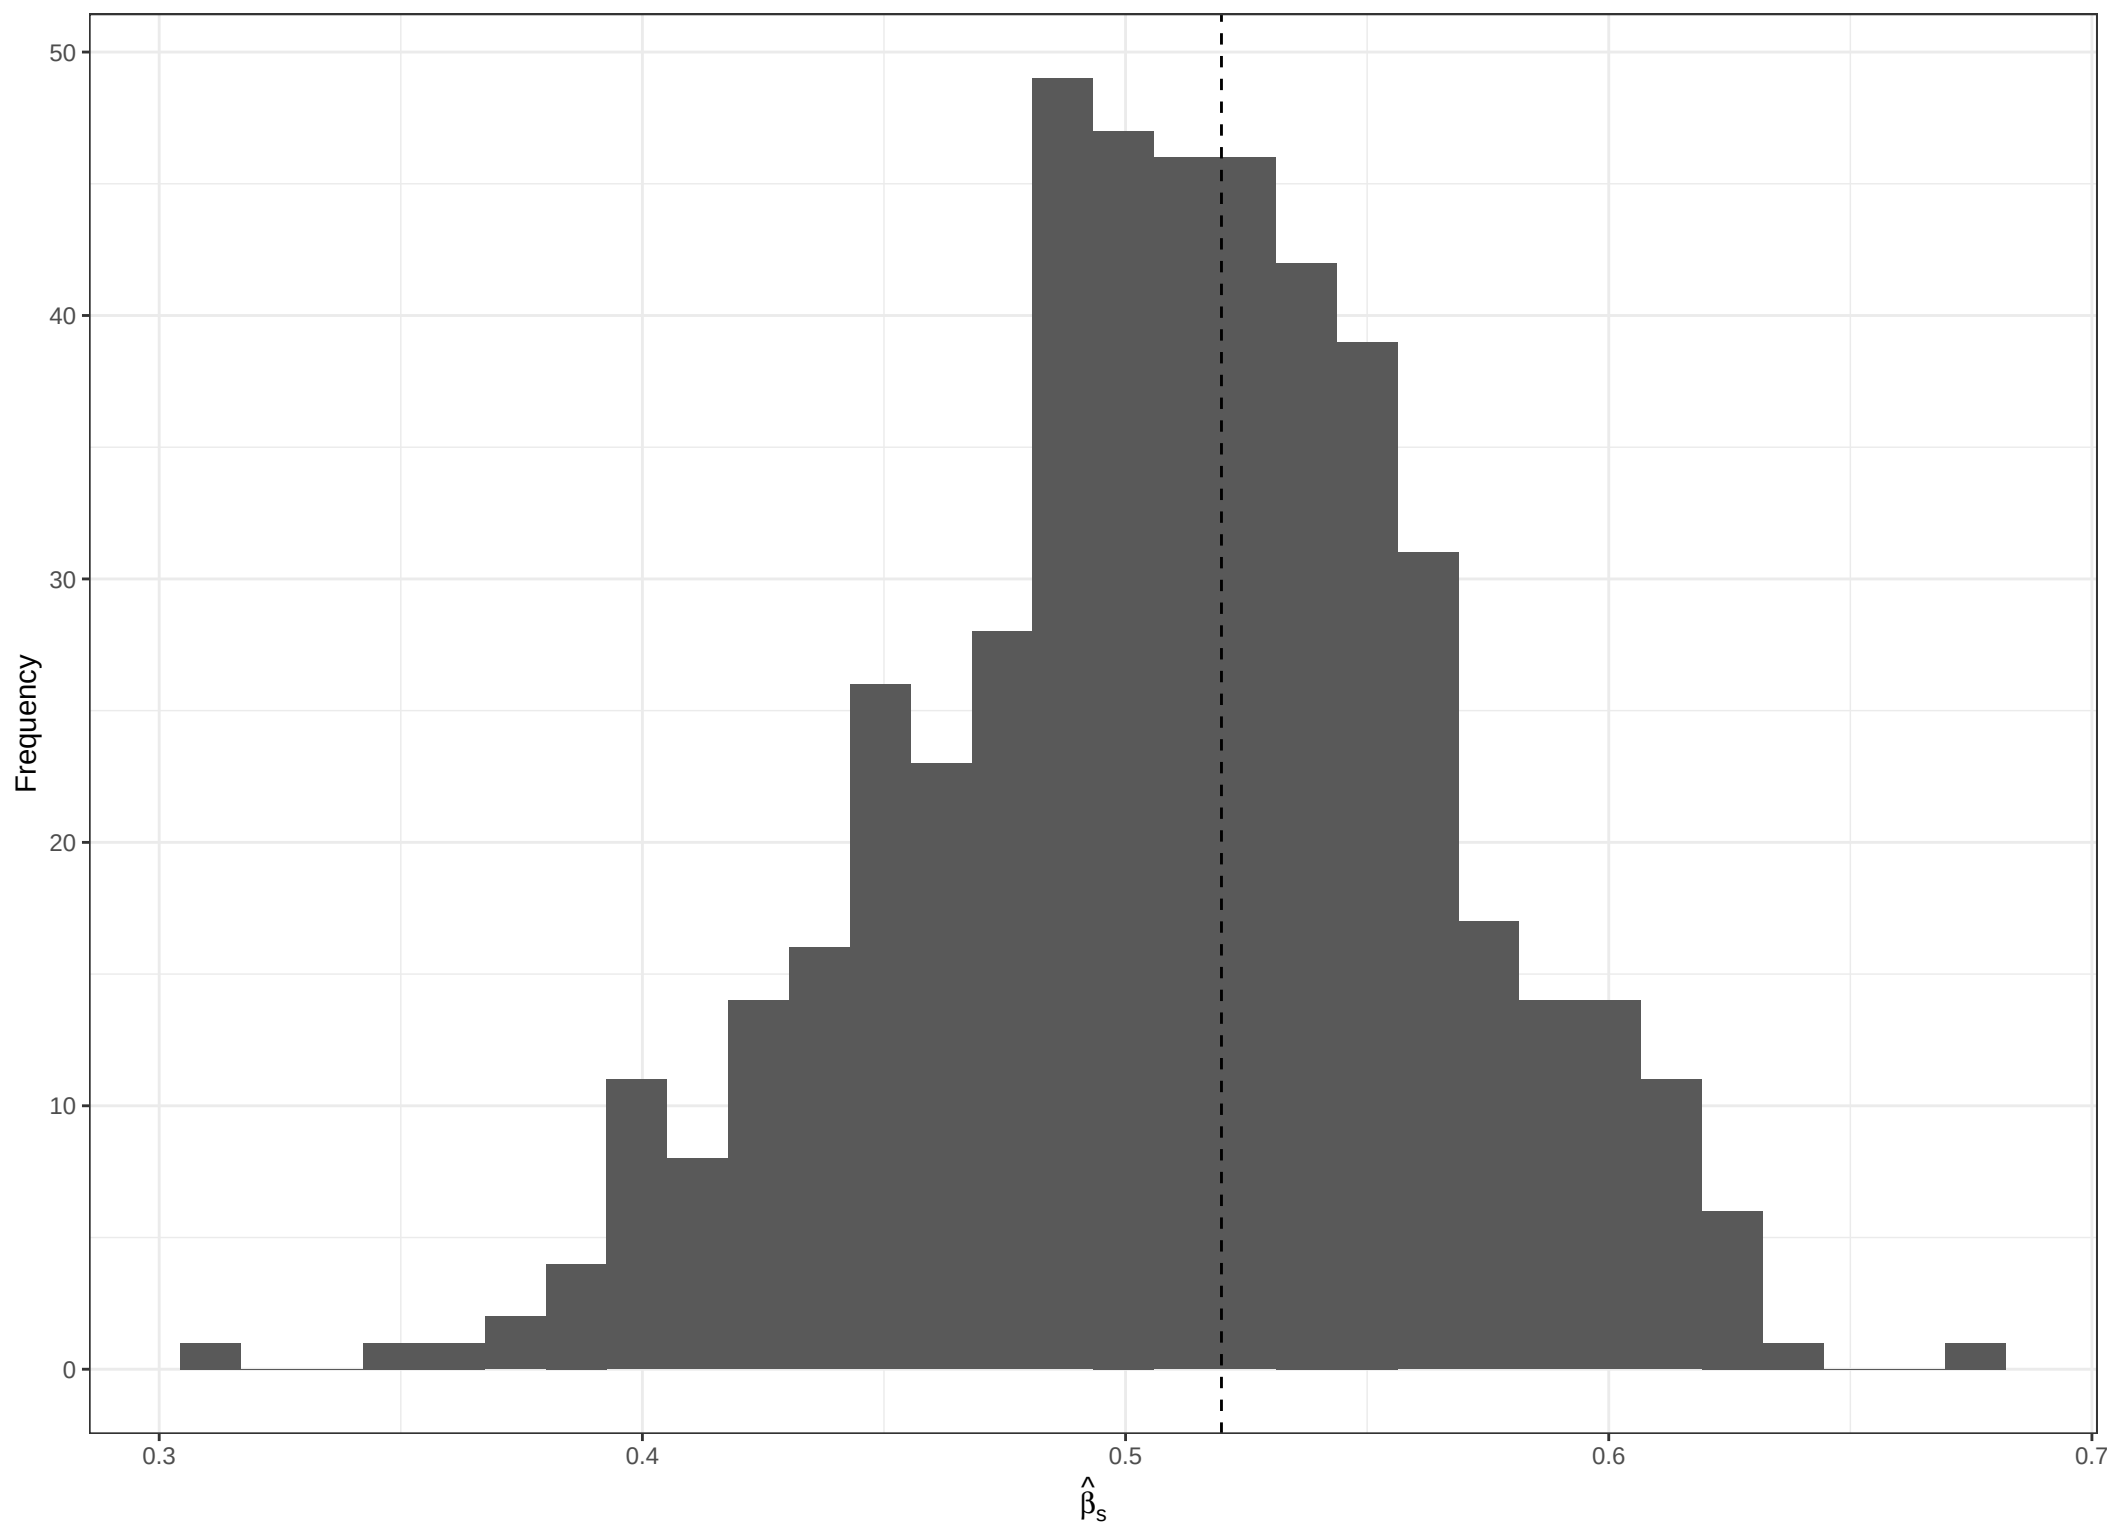

Positive values favour SS-SPAOM; bars are process-bootstrap 95% intervals

Comparator and metric

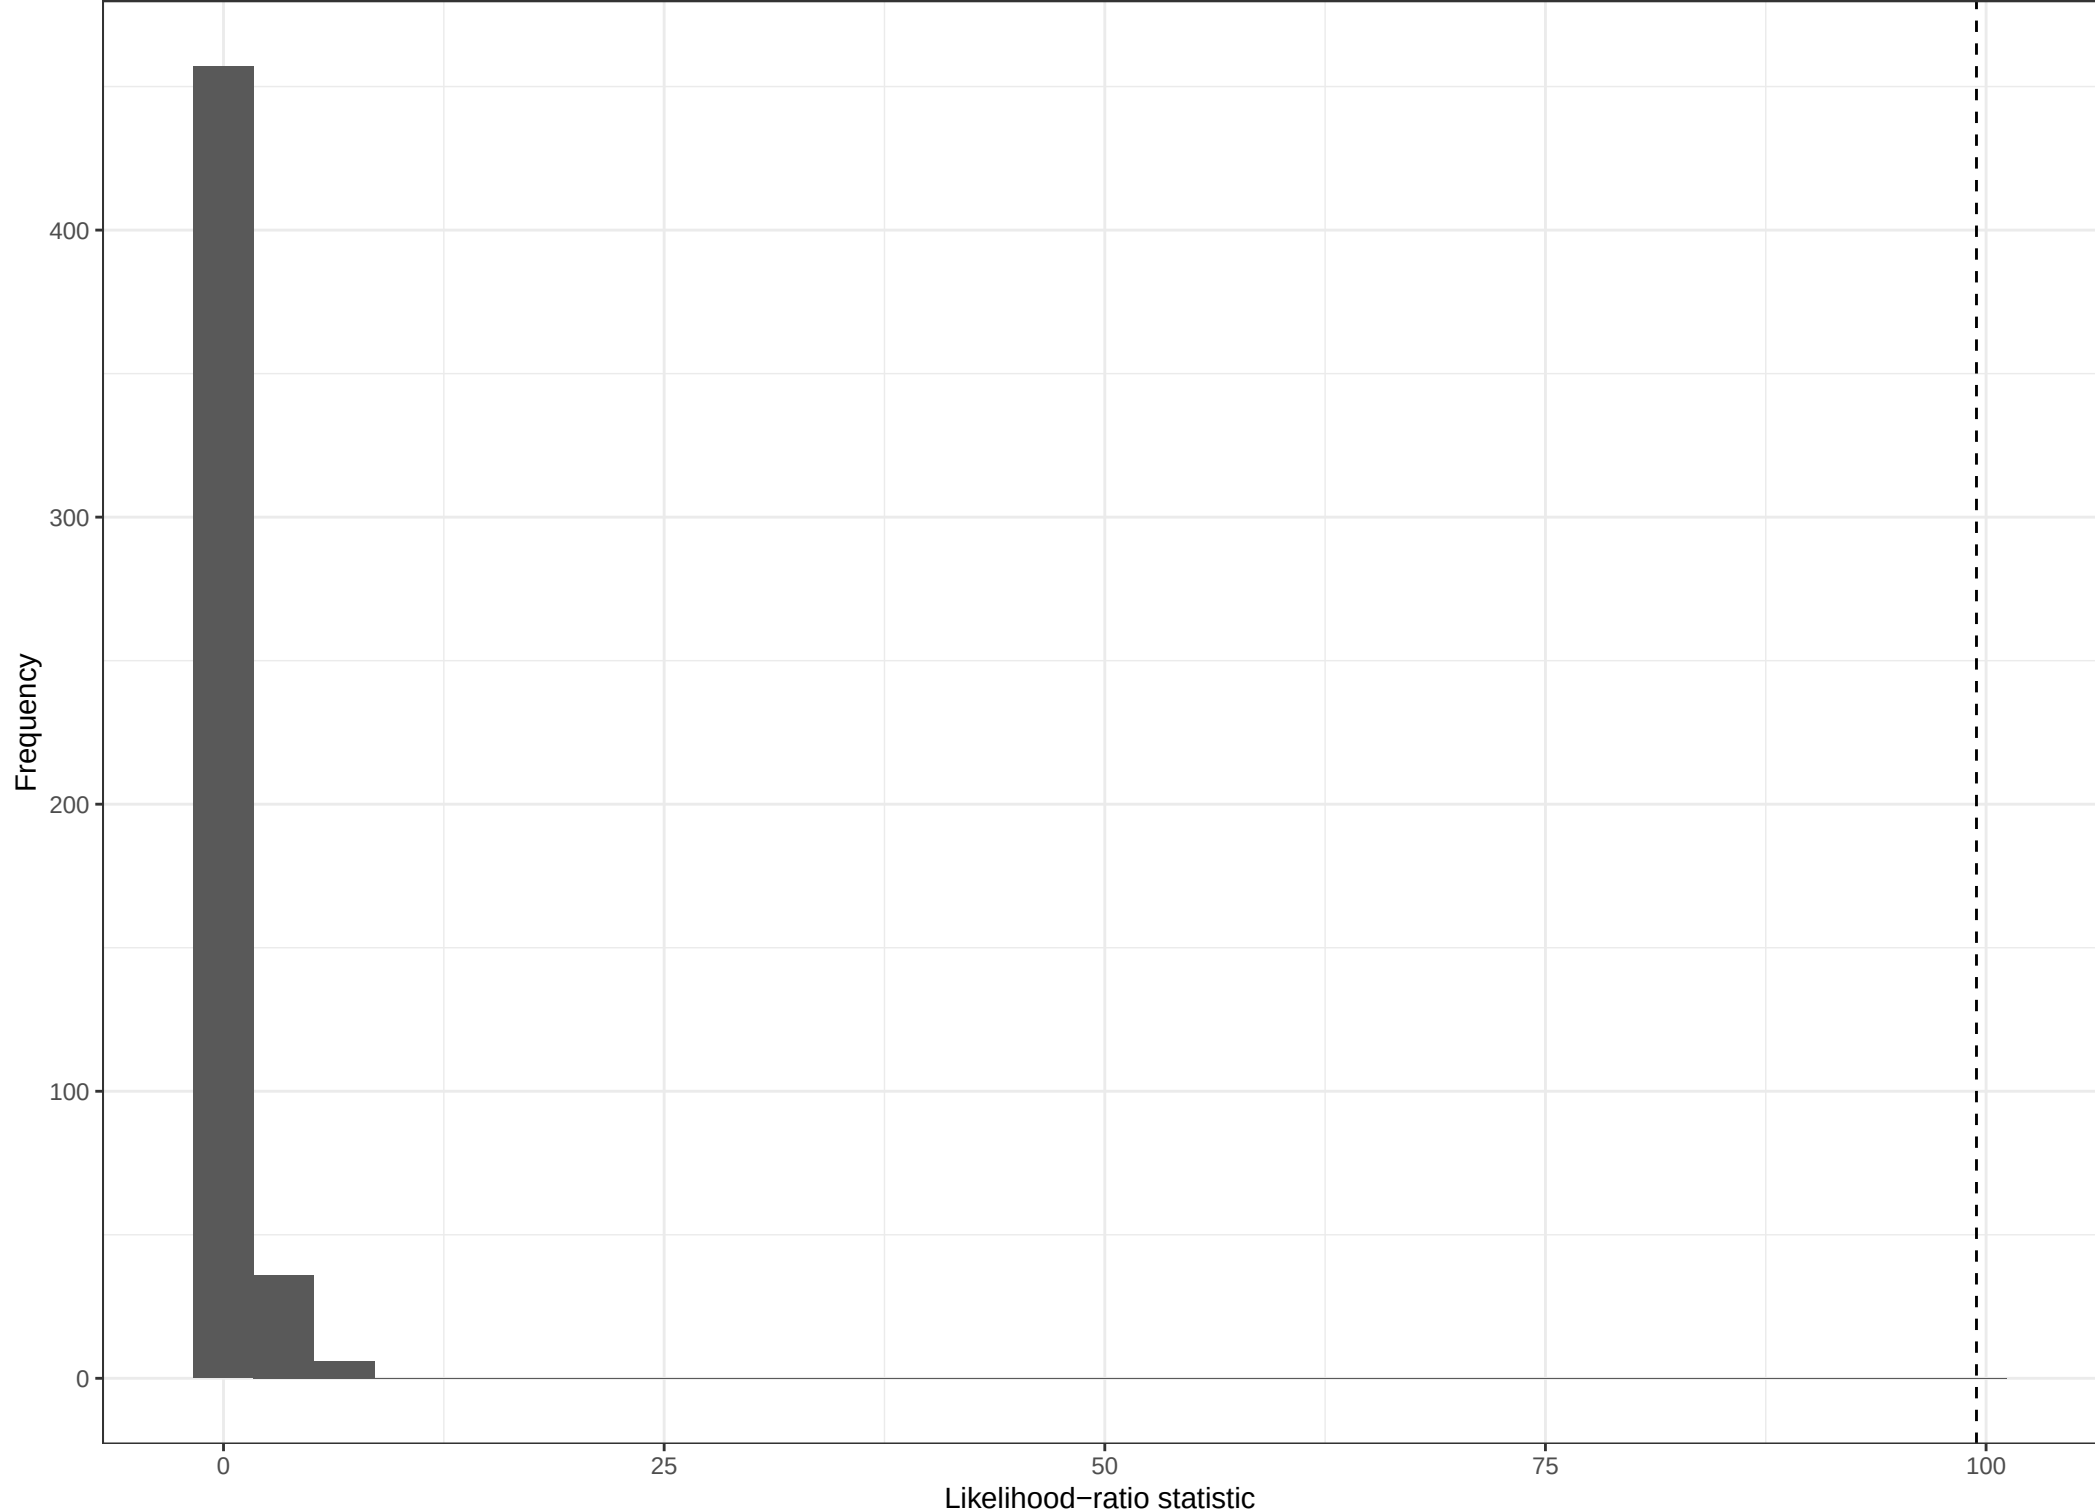

Process-bootstrap distribution of the stage-spell effect

Dashed line marks the full-data estimate

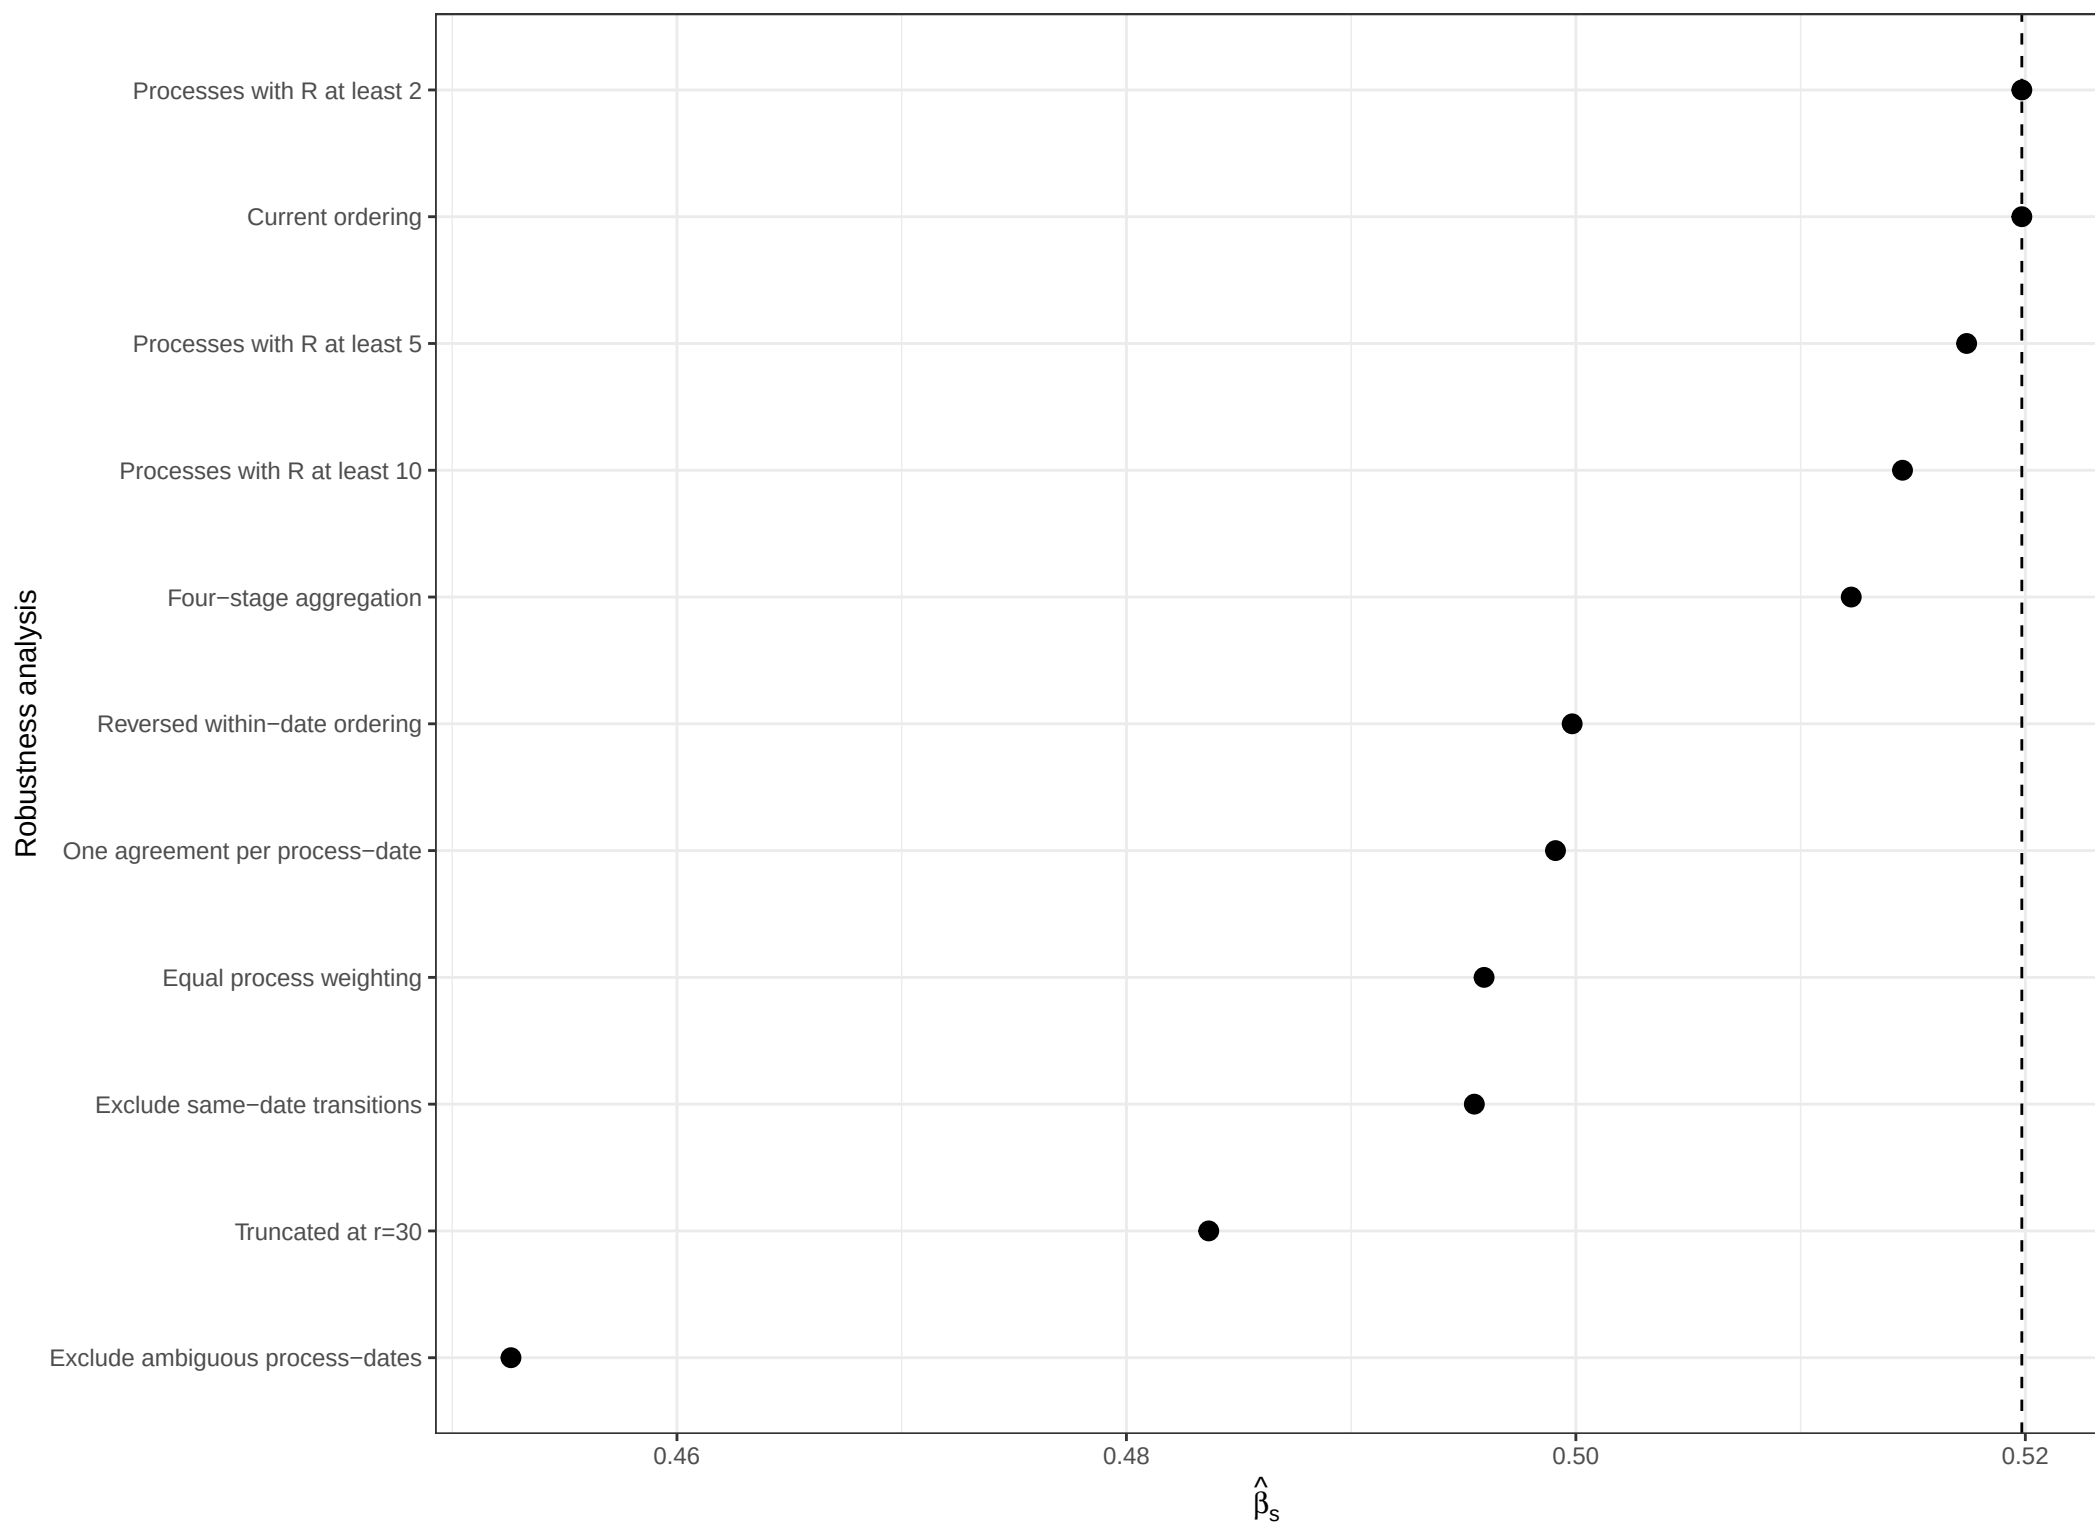

Parametric-bootstrap null distribution for the stage-spell LR statistic

Dashed line marks the observed statistic

Robustness of the estimated stage–spell effect

Dashed line marks the primary estimate

Most influential peace processes for the stage–spell estimate
